

Fig. S1. Photomicrograph showing epidermal characteristics of seborrheic keratosis with papillomatosis, acanthosis and hyperkeratosis with pseudocornoid cysts. Widespread nests of pleomorphic epithelial cells with partially bright vacuolated cytoplasm and focal acantholysis, as well as multiple atypical mitosis in the epidermis, but predominantly more subepidermal. Deeper dermal layers with separated cell clusters, partly within dilated lymphatic vessels (HE, original magnification $\times 400$).
