

Fig. S2. Results of the questionnaires used in relation to concealing of vitiligo ( $n=96$ ): never ( $n=11$ , 11.5%), very rarely ( $n=22$ , 22.9%), quite often ( $n=34$ , 35.4%), very often ( $n=29$ , 30.2%). There is a strong relationship between frequency of avoidance behaviour and scores of all questionnaires used in this study. High scores go along with high frequency of concealing the white spots in front of other people. Levels of significance measured by a one-way ANOVA test.
