Supplementary material to article by I. Jalenques et al. “High Prevalence of Personality Disorders in Skin-restricted Lupus Patients”

Fig. S1. Flow chart of the data selection for personality disorder analyses. In this study, 80 patients and 160 controls matched for sex, age and educational level were recruited (2 controls for 1 patient). Twenty patients were excluded from analyses because of non-assessable data, suspect questionnaire responses and non-corrected questionnaires. We used the optimal version of Personality Diagnostic Questionnaire 4 (PDQ4), which includes the clinical significance scale (CSS). The 40 controls matched with these patients were also excluded. In addition, data of 2 controls were rejected because of one suspect questionnaire and one questionnaire without CSS correction. Thus, two patients had only one control.
