Supplementary material to article by W. Francuzik et al. "Propionibacterium acnes Abundance Correlates Inversely with Staphylococcus aureus: Data from Atopic Dermatitis Skin Microbiome."

Fig. S1. Relative abundances of the 10 most abundant species sampled from 3 skin locations of 7 patients with atopic dermatitis (AD) and 7 healthy controls. Less abundant species were grouped together into “others” and included in the graph for completeness. The samples are coded as follows: patient number and sampling area. Sample 005-AF and 005-AFL were taken from locations close to each other (< 3 cm) and were from lesional and non-lesional skin, respectively. Samples were sorted according to the relative P. acnes abundance. AF: antecubital fossa; RA: retroauricular; IS: interscapular.
