

Table SII. Summary: Clinical, dermoscopic and histopathological characteristics of double-ended pseudocomedones (DEP) as compared to open comedones

	Double-ended pseudocomedones	Open comedones
Localization	Areas of previous hidradenitis suppurativa inflammatory lesions	Seborrhoeic areas
Clinical aspect	Rarely single, more often multiple, coupled tiny cavities, usually showing a blackhead at each end	Single or multiple papules with a blackhead
Dermoscopy	Coupled hollows deepening in a slanted or parallel fashion respect to the skin surface within a whitish cicatricial tissue, presenting large, irregular openings and keratin accumulation, either deep-seated or superficially located	Superficial, follicular papules with a central, roundish opening filled with a keratotic plug, generally overlying a regular flat epidermis
		
Histopathology	Cavities lined by normal multilayered epithelium and filled with corneal lamellae, cellular debris and amorphous material, in which the hair follicles are no more detectable	Widened hair follicle filled with keratin
