Sir,
We applaud the research efforts of the Italian group evaluating the psychosocial effects of psoriasis using the Life Quality Index (1). This aspect of the disease, often overlooked by the average therapist, is extremely important for the management of the whole patient. In addition to the tests applied above, we suggest that clinicians also consider our Human Figure Drawing assessment reported in the psychological literature in 1981 (2). This rapidly administered and scored measure is sensitive to identifying body image concerns of patients with severe psoriasis and can enhance the therapist’s understanding of ways in which psoriasis affects perceptions and feelings about oneself. It is easy and fun to conduct.
