Objective: To improve, with the aid of psychometric analysis, the Balance Evaluation Systems Test (BESTest), a tool designed to analyse several postural control systems that may contribute to poor functional balance in adults.

Methods: Performance of the BESTest was examined in a convenience sample of 115 consecutive adult patients with diverse neurological diagnoses and disease severity, referred to rehabilitation for balance disorders. Factor (both explorative and confirmatory) and Rasch analysis were used to process the data in order to produce a new, reduced and coherent balance measurement tool.

Results: Factor analysis selected 24 out of the 36 original BESTest items likely to represent the unidimensional construct of “dynamic balance”. Rasch analysis was then used to: (i) improve the rating categories, and (ii) delete 10 items (misfitting or showing local dependency). The model consisting of the remaining 14 tasks was verified with confirmatory factor analysis to meet the stringent requirements of modern measurement.

Conclusion: The new 14-item scale (dubbed mini-BESTest) focuses on dynamic balance, can be conducted in 10–15 min, and contains items belonging evenly to 4 of the 6 sections from the original BESTest. Further studies are needed to confirm the usefulness of the mini-BESTest in clinical settings.

Key words: postural balance, outcome assessment, psychometrics.
MATERIAL AND METHODS

Patients
A total of 115 patients (53 men and 62 women), mean age 62.7 years (standard deviation, (SD) 16), were studied. They represent a convenience sample of patients with balance disorders, recruited with a consecutive sampling method. Patient diagnosis was as follows: 22 hemiparesis (12 right, 10 left), 21 Parkinson’s disease, 15 neuromuscular diseases, 14 hereditary ataxia, 11 multiple sclerosis, 10 unspecified age-related balance disorders, 7 peripheral vestibular disorders, 6 traumatic brain injury, 4 diffuse encephalopathy, 3 cervical myelopathy, and 2 central nervous system (CNS) neoplasm. All subjects were inpatients referred to the Scientific Institute of Veruno for rehabilitation assessment and treatment. Inclusion criteria were: ability to walk with or without a cane; absence of severe cognitive or communication impairments; ability to tolerate the balance tasks without fatigue. Prior to taking part in the study, all participants signed an informed consent that had been approved by the central ethics committee of the “Salvatore Maugeri” Foundation.

Instrument and procedure
The BESTest (7) contains 6 subscales, covering a broad spectrum of performance tasks: (I) biomechanical constraints, (II) stability limits, (III) transitions and anticipatory postural adjustments, (IV) postural responses to perturbation, (V) sensory orientation while standing on a compliant or inclined base of support, and (VI) dynamic stability in gait with and without a cognitive task (Table I). The BESTest consists of 27 items, some of which are subdivided into 2–4 sub-items (e.g. for left and right sides) for a total of 36 tasks. Each item is scored on a 4-category ordinal scale from 0 (worst performance) to 3 (best performance). Specific patient and rating instructions, and stopwatch and ruler values are used to improve reliability (see www.bestest. us). Patients were rated by a physical therapist (MG) with 4 years of practice experience in balance assessment, who participated in a one week training course on the BESTest, at the Balance Disorders Laboratory, Oregon Health & Science University.

Statistical analysis
Unidimensionality, i.e. whether items are measuring a single underlying dimension or several separate dimensions, is one of the key requisites for test analysis and must be verified before applying Rasch models (13). To test the dimensionality of the BESTest, we performed the following statistical steps.

1. A confirmatory factor analysis for categorical data (CFA, LISREL 8.80 software, Scientific Software International, Inc., Lincolnwood, IL 60712, USA) was performed to evaluate the fit of the scale to a unidimensional model. The extent to which the model can be used to reproduce the sample data was determined by examining the following indexes: the non-normed fit index (NNFI, or Tucker-Lewis index), the comparative fit index (CFI), the root mean square error of approximation (RMSEA) and the standardized root mean square residual (SRMR). NNFI and CFI scores range from 0 to 1 with higher values indicating better fit: values greater than 0.95 are indicative of an acceptable model fit. A RMSEA value lower than 0.08 reflects an adequate fit and a RMSEA value equal to or less than 0.05–0.06 suggests a good fit. A SRMR value between < 0.10 and 0.05 is reflective of an acceptable fit (14–15).

2. In the event of a poor fit (i.e. multidimensionality is suspected) the following statistical steps were performed sequentially:
   a. Horn’s parallel analysis (16) was used to estimate the number of meaningful dimensions in the response matrix; the size of eigenvalues obtained from principal component analysis (PCA) was compared with those obtained from a randomly generated data set of the same size and number of variables. Only factors with eigenvalues exceeding the values obtained from the corresponding random dataset were retained for further investigation. Parallel analysis was conducted using ViSta (17) Parallel Analysis plugin (http://www.mdp.edu.ar/psicologia/vista/).
   b. Exploratory factor analysis (EFA, STATA 10.1 software, Stata-Corp LP College Station TX 77845, USA) was performed with a principal factor analysis using the number of factors suggested

Table 1. Summary of BESTest items and subsystem categories. The 14 items forming the mini-BESTest for dynamic balance are in bold. Only the worst performance in items 11 “Stand on one leg” and 18 “Lateral stepping” have to be taken into account for the score. Moreover, the performance in item 27 “Cognitive Get Up and Go” must be compared with that in the baseline item 26.

by the parallel analysis. After varimax rotation, the relationships between the test items and retained factors were taken into account. For a solution that is stable and approximates the population pattern, given the sample size, only items with loading >0.50 were considered as correlated to the factors (18).

c. Item exclusion, based on the EFA results and expert review, was performed leading to a preliminary reduced set of test items. Following the above analysis and item exclusion, the matrix of item responses of the 24 retained items for each subject underwent Rasch analysis using WINSTEPS software (Linacre JM, WINSTEPS Rasch measurement computer program, version 3.68. Winsteps. com; 2009) (19).

As a first step, we investigated whether the rating scale of each BESTest item was used in the expected manner. We evaluated the rating scale categories (partial credit model) using criteria suggested by Linacre (20, 21): (i) at least 10 observations per response option; (ii) even distribution of category use; (iii) monotonic increase in both average measures of persons with a given score/category and thresholds (thresholds, or step calibrations, are the ability levels at which the response to either of 2 adjacent categories is equally likely); (iv) statistics are expected to approach 1 if the data fit the model expectancies. Both of these fit statistics (MnSq) for each item were calculated to test whether there were items that did not fit the model expectancies. We collapsed categories following these guidelines, and compared different collapsing solutions, examining not only the category diagnostics, but also reliability indices. We were guided by the intention to select a solution that maximized statistical indices and clinical meaningfulness.

After this rating scale modification, a new Rasch analysis was performed, including PCA on the standardized residuals to evaluate: (i) the presence of sub-dimensions, as an independent confirmation of the unidimensionality of the scale, and (ii) the local independence of items.

1. “Unidimensionality” assumes that, after removal of the trait that the scale intended to measure (the “Rasch factor”), the residuals will be uncorrelated and normally distributed (i.e. there are no principal components) (19). The following criteria were used to determine whether additional factors were likely to be present in the residuals: (i) a cutoff of 50% of the variance explained by the Rasch factor; and (ii) eigenvalue of the first residual factor smaller than 3 (19).

2. “Local independence” between items indicates that they do not duplicate some feature of each other or they both incorporate some shared dimension. Item couples with a standardized residual correlation > 0.30 were considered as possibly dependent components (22). Based on examination of the respective item information functions and expert judgement, we progressively eliminated all dependencies, either removing one of the items, or, in the case of dependent items that were related to the same task performed in different directions (e.g. scores assessing right and left sides), collapsing the items into a new one reporting only the worst performance.

Internal validity of the scale was assessed by evaluating the fit of individual test items to determine if the pattern of item difficulty was consistent with the model predictions. We estimated the goodness-of-fit of the observed data to data predicted by the Rasch model (23, 24).

Information-weighted (infit) and outlier-sensitive (outfit) mean-square statistics (MnSq) for each item were calculated to test whether there were items that did not fit the model expectations. Both of these fit statistics are expected to approach 1 if the data fit the model. In accordance with the literature (10), we considered MnSq > 0.7 and < 1.3 as an indicator of acceptable fit. We also estimated the level of difficulty of each item (“item difficulty”) and the ability of each individual subject, and then we examined the data for floor and ceiling effects. Item difficulty and subject ability are expressed, on a common interval scale, in logit units, a logit being the local independence of items.

In a variety of functional conditions. These 24 items underwent Rasch analysis.

Reliability was evaluated in terms of “separation” across test items, defined as the ratio of the true spread of the measures to their measurement error (23, 24). Two indexes were calculated: the item separation index and the person separation index, that give an estimate (in standard error units) of the spread or “separation” of items and persons along the measurement construct, respectively. A separation of 2.0 is considered good (24). Related indexes are the reliability of the item separation index and of the person separation index. These provide the degree of confidence that can be placed in the consistency of the estimates. This confidence ranges from 0 to 1, and coefficients > 0.80 and > 0.90 are considered respectively good and excellent (23).

RESULTS

The confirmatory factor analysis (CFA) gave, using all the items in the BESTest, an adequate fit (NNFI = 0.91, CFI = 0.91, RMSEA = 0.12, SRMR = 0.15). Horn’s Parallel Analysis (PA) revealed 3 factors with empirical eigenvalues exceeding those from the random data. These 3 factors explained 43%, 11% and 8% of the variance, respectively. To investigate the contribution of each item to the scale, we tested the 3-factor model suggested by PA using exploratory factor analysis for ordinal data (EFA) with a principal axis factor extraction method. After varimax rotation, 24 items loaded > 0.50 in the first factor, 4 items (6 a–d) in the second factor, and 3 items (7, 8a and 8b) in the third factor, while items 1–4 and 13 failed to load meaningfully in any factor.

Taking into account these results and expert opinion, 12 items (1–4, 6a–d, 7, 8a–b, 13) were deemed as not belonging to the main trait and therefore were dropped from subsequent analyses. The expert review judged the remaining 24 items to potentially measure a factor likely to represent “dynamic balance” in a variety of functional conditions. These 24 items underwent Rasch analysis.

Rating scale diagnostics showed that the 0–3 level rating categories did not comply with our pre-set criteria for category function. The model best meeting the criteria reduced the rating scale from 4 to 3 levels by combining categories 0 (absent) and 1 (mild) or 1 (mild) and 2 (moderate) (Table II), with different collapsing strategies used across items.

After combining these rating scale categories, 22 out of the 24 items fitted the underlying construct of dynamic balance that the scale was intended to measure (infit and outfit MnSq between 0.7 and 1.3). Item 5 “Sit on floor and stand up” was underfitting (i.e. with unexpectedly high variability) and item 26 “Get up and go” was overfitting (i.e. with an overly predictable pattern), so they were eliminated.

The PCA of standardized residuals showed several high (>0.30) residual correlations between items.

Based on examination of the respective item information functions and expert judgment, all misfitting items and residual correlations > 0.30 were eliminated one by one, and the Rasch analysis was re-run. Correlated (redundant) items were removed either by deleting one of them, or by maintaining only the worst performance in items 11 and 18, which assessed the same task on both right and left side. At the end of these iterations, only 14 test items remained. This set of items (called the mini-Balance Evaluation Systems Test of dynamic balance; mini-BESTest) (see Table I) underwent further analyses.

J Rehabil Med 42
All of the final 14 items showed good infit and outfit MnSq values (Table II). The variance explained by the estimated Rasch measures was 58.8%, whereas only 5.3% of the variance was explained by the first residual factor (eigenvalue 1.8). Regarding the hierarchic ordering of items, Figs 1 and 2 show, according to the Rasch model, the distribution of subject ability and item difficulty. Item difficulty showed a fairly even spread (from the most easy item “Stand with eyes open on a firm surface” to the most difficult item “Stand on one leg”), and subject ability presented a normal distribution spanning from –5 to +4.9 logits, with an average measure = +0.15 (mean SE 0.59). Only 2 subjects showed extreme maximum scores: the precision of their ability estimates was quite low, the SE being approximately 30% of the corresponding measure. No floor effect was found. Overall, these findings demonstrate an adequate sample-item distribution. The item difficulty estimates spanned from –4 to +2.5 logits. The reliability indices of mini-BESTest were as follows: item separation index = 7.35 and item separation reliability = 0.98; Person separation in-dex = 2.50 and Person separation reliability = 0.86.

A final CFA confirmed the unidimensionality of the mini-BESTest, supporting the unidimensional model with the following indexes: NNFI = 0.98, CFI = 0.99, RMSEA = 0.064, and SRMR = 0.098.

The final version of the mini-BESTest is shown in Appendix I.

Table II. Mean difficulty estimates for each of the 14 items of the mini-BESTest with standard errors (SE) and infit and outfit mean-square statistics (MnSq). The more difficult the item estimate, the less likely it is for any subject to gain a high score. Alongside each item is its number in the original BESTest (see Table I). The rating scale column shows how the 4 scaling categories were collapsed into 3 categories, e.g. 0012 means that categories 0 and 1 have been collapsed and then the remaining 3 categories have been re-numbered accordingly. L: left; R: right; EO: eyes open; EC: eyes closed.

DISCUSSION

The original BESTest is composed of a comprehensive battery of 36 balance tasks, developed to analyse 6 different postural control systems that may contribute to poor functional balance in adults of any age (7). Thus, it is not surprising that this test failed to meet a unidimensionality assumption (i.e. that a single dimension underlies all item responses), when applied to 115 patients with a wide range of diagnoses and severity of disease.

Our dimensionality assessment extracted from the test battery 24 item assumed to define “dynamic balance”. On these
items we performed an analysis of category and item properties using Rasch psychometric methods, which led to the definition of the 14 most psychometrically useful and practical items: the refined mini-BESTest measures the unidimensional construct of “dynamic balance” without redundant items or significant ceiling/floor effects (26) and takes 10–15 min to administer.

The rating scale diagnostics (21) performed on the 24 items retained after EFA showed that the original 4 levels were redundant (23). This finding was expected, since some BESTest items were borrowed (with modifications) from the BBS and the Dynamic Gait Index. These 2 well-known balance and mobility scales have been shown to include sub-optimal category functioning (27, 28) when strict diagnostic criteria are applied (20). In addition, it has already been demonstrated that the BBS (and other balance scales) show essentially identical psychometric properties, including responsiveness, when used with a 3-category, instead of a 4- or 5-category rating scale (29). Appropriate combination of levels 0–1 or 1–2 eliminated underutilized rating categories, and ensured that each rating category was distinct from the others in representing a distinct balance ability.

After collapsing the categories to 3 distinct levels, the data from the 24-item set were reanalysed to calculate fit statistics and the PCA of the residuals. This analysis enabled us to eliminate 10 misfitting or redundant items without loss of measurement information and with the great advantage of improving test acceptability and feasibility. For the remaining 14-item (the mini-BESTest), we calculated fit statistics, extracted Rasch-modelled parameters of ability and difficulty, and then examined internal validity and test reliability. The average ability of this group of patients was very similar to the mean value of 0 logits (+0.15): this means that the test is well targeted to the sample. Moreover, the person-ability and item-difficulty mapped logit scale showed a broad range for both person-ability and item-difficulty (Fig. 1). The 1.7% of subjects (2/115) with extreme maximum scores, the 2 “×” at the top of the left-hand column in Fig. 1, constituted a minor trend toward a ceiling effect in very highly functioning subjects. No floor effect was found. However, one should interpret the extreme results with caution, since these person measures have the least precision due to the larger errors of measurement. On the other hand, the high item separation reliability indicates that great confidence can be placed in the consistency of item difficulty estimate across future samples.

Content validity of the dynamic mini-BESTest is high, since many items included in the test are part of well-known balance batteries: (i) “Sit to stand” is from the Berg Balance Scale (30) and the Performance-Oriented Mobility Assessment (31); (ii) “Stand on one leg” is from the Ataxia Test Battery (32) and the Berg Balance Scale; (iii) “Stance – eyes open” and “Stance on foam – eyes closed” are from the modified Clinical Test of Sensory Integration of Balance (33, 34); (iv) Gait when balance is challenged by changing speed, head rotations, pivot turns, or stepping over obstacles comes from the Dynamic Gait Index (35); (v) the “Get Up and Go” test (36) and the “Get Up and Go with a simultaneous cognitive task” (37) are stand-alone tests. In the BESTest, Horak et al. (7) made only minor modifications to some of the above original items, in order to increase their challenge and improve their consistency and reliability. Novel items in the mini-BESTest have been adapted from laboratory tests where they were shown to distinguish different types of balance disorders: (i) postural reactions to external perturbations (38); (ii) rise to toes (39); and (iii) stance on an inclined surface with eyes closed (40).

As an additional demonstration of the internal construct validity of the scale, the general hierarchical arrangement found by Rasch analysis (Table II) is consistent with clinical expectations. For example, the maintenance of feet-together stance, eyes open on a firm surface (“Stance EO”) is the easiest task and “Stand on one leg” the most difficult task item (28). In fact, “Stance EO” makes few sensory demands and requires low effort, whereas “Stand on one leg” is very challenging because of the narrow base of support and musculoskeletal demands. In addition, the results of Rasch analysis of the mini-BESTest show a hierarchical order of item difficulty: “Gait with hori-
vertical head turns", “Stand on one leg”, and “Lateral stepping responses” were the most difficult items, whereas “Stance EO” and “Sit to Stand” were the easiest items. The high difficulty of the item “Gait with horizontal head turns” may be attributed to vestibular influences (35) and is in line with the results of the two Rasch studies on the Dynamic Gait Index (28, 41).

The mini-BESTest contains 14 items belonging evenly to 4 of the 6 sections from the original BESTest (Table I): section III “Anticipatory Postural Adjustments” (sit to stand, rise to toes, stand on 1 leg); section IV “Postural Responses” (stepping in 4 different directions); section V “Sensory Orientation” (st ance – eyes open; foam surface – eyes closed; incl ine – eyes closed); and section VI “Balance during Gait” (gait during change speed, head turns, pivot turns, obstacles; cognitive “Get Up and Go” with dual task).

Our factor analysis procedure (42) isolated a number of items, primarily in the first 2 sections of the BESTest, that did not contribute to the dominant trait (dynamic balance), suggesting that parts I “Biomechanical constraints” and II “Stability limits” of the BESTest warrant separate psychometric studies. Biomechanical constraints (such as orthopaedic limitations on the base of foot support, postural alignment and strength) and stability limits (ability to lean to perceived limits of stability and perception of verticality) are also important facets of postural control, but appear to be independent of the construct “dynamic balance”.

This study has several limitations, which restrict the generalization of our results to different groups or settings, and raters. In particular, the selection criteria of our convenience sample (recruited with a consecutive sampling method) may restrict the generalizability of results he participated in a one week training course on BESTest, held by one of its developers (FBH).

In conclusion, the new mini-BESTest offers a unique, brief clinical rating scale for dynamic balance that has excellent psychometric characteristics. The potential interest of the mini-BESTest in clinical settings is high, but further studies are needed. They should include: (i) analysis of the actual performance of the new 3-level response structure; and (ii) a study of differential item functioning, i.e. the stability of item hierarchy across subsamples defined according to potentially relevant clinical criteria; (iii) relation of the scores to fall risk and to other clinical tests of balance; and (iv) age-related normative values.

APPENDIX I. Mini-BESTest of Dynamic Balance – Balance Evaluation System’s Test© 2009

Subjects should be tested with flat-heeled shoes OR shoes and socks off. If subject must use an assistive device for an item, score that item one category lower. If subject requires physical assistance to perform an item, score the lowest category (0) for that item.

1. SIT TO STAND
(2) Normal: Stable for 3 s with maximum height.
(1) Moderate: Comes to stand WITH use of hands on first attempt.
(0) Severe: Impossible to stand up from chair without assistance, OR several attempts with use of hands.

2. RISE TO TOES
(2) Normal: Stable for 3 s with maximum height.
(1) Moderate: Heels up, but not full range (smaller than when holding hands), OR noticeable instability for 3 s.
(0) Severe: ≤3 s.

3. STAND ON ONE LEG
Left Time in Seconds Trial 1: _____ Trial 2: _____
(2) Normal: 20 s.
(1) Moderate: <20 s.
(0) Severe: Unable.

Right Time in Seconds. Trial 1: _____ Trial 2: _____
(2) Normal: 20 s.
(1) Moderate: <20 s.
(0) Severe: Unable.

4. COMPENSATORY STEPPING CORRECTION – FORWARD
(2) Normal: Recovers independently a single, large step (second realignment step is allowed)
(1) Moderate: More than one step used to recover equilibrium.
(0) Severe: No step, OR would fall if not caught, OR falls spontaneously.

5. COMPENSATORY STEPPING CORRECTION – BACKWARD
(2) Normal: Recovers independently a single, large step.
(1) Moderate: More than one step used to recover equilibrium.
(0) Severe: No step, OR would fall if not caught, OR falls spontaneously.

6. COMPENSATORY STEPPING CORRECTION – LATERAL
Left
(2) Normal: Recovers independently with 1 step (crossover or lateral OK).
(1) Moderate: Several steps to recover equilibrium.
(0) Severe: Falls, or cannot step.

Right
(2) Normal: Recovers independently with 1 step (crossover or lateral OK).
(1) Moderate: Several steps to recover equilibrium.
(0) Severe: Falls, or cannot step.

7. STANCE EYES OPEN, FIRM SURFACE (FEET TOGETHER)
Time in seconds: _____
(2) Normal: 30 s.
(1) Moderate: <30 s.
(0) Severe: Unable.
8. STANCE EYES CLOSED, FOAM SURFACE (FEET TOGETHER)

*Time in seconds:* 

(3) Normal: 30 s.
(1) Moderate: <30 s.
(0) Severe: Unable.

9. INCLINE – EYES CLOSED

*Time in seconds:* 

(2) Normal: Stands independently 30 s and aligns with gravity.
(1) Moderate: Stands independently <30 s, OR aligns with surface.
(0) Severe: Unable.

10. CHANGE IN GAIT SPEED

(2) Normal: Significantly changes walking speed without imbalance.
(1) Moderate: Unable to change walking speed or imbalance.
(0) Severe: Unable to achieve significant change in speed AND signs of imbalance.

11. WALK WITH HEAD TURNS – HORIZONTAL

(2) Normal: performs head turns with no change in gait speed and good balance.
(1) Moderate: performs head turns with reduction in gait speed.
(0) Severe: performs head turns with imbalance.

12. WALK WITH PIVOT TURNS

(2) Normal: Turns with feet close, FAST (≤3 steps) with good balance.
(1) Moderate: Turns with feet close SLOW (≥4 steps) with good balance.
(0) Severe: Cannot turn with feet close at any speed without imbalance.

13. STEP OVER OBSTACLES

(2) Normal: Able to step over box with minimal change of speed and with good balance.
(1) Moderate: Steps over shoe boxes but touches box, OR displays cautious behaviour by slowing gait.
(0) Severe: Cannot step over shoe boxes, OR hesitates, OR steps around box.

14. TIMED GET UP & GO (TUG) AND COGNITIVE GET UP & GO WITH DUAL TASK:

*TUG:* _______ seconds; *Dual Task TUG:* _______ seconds

(2) Normal: No noticeable change between sitting and standing in backward counting and no change in gait speed compared with TUG with dual task.
(1) Moderate: Dual task affects either counting OR walking.
(0) Severe: Stops counting while walking OR stops walking while counting.

**INSTRUCTIONS**

1. **Sit to Stand**

*Examiner Instructions:* Note the initiation of the movement, and the use of hands on the arms of the chair or their thighs or thrusts arms forward.

*Patient:* Cross arms across your chest. Try not to use your hands unless you must. Do not let your legs lean against the back of the chair when you stand. Please stand up now.

2. **Rise to toes**

*Examiner Instructions:* Allow the patient to try it twice. Record the best score. (If you suspect that subject is using less than their full height, ask them to rise up while holding the examiners' hands.) Make sure subjects look at a non–moving target 4–12 feet away.

*Patient:* Place your feet shoulder width apart. Place your hands on your hips. Try to rise as high as you can onto your toes. I will count out loud to 3 seconds. Try to hold this pose for at least 3 seconds. Look straight ahead. Rise now.

3. **Stand on one leg**

*Examiner Instructions:* Allow the patient two attempts and record the best. Record the number of seconds they can hold posture up to a maximum of 30 seconds. Stop timing when subject moves their hand off hips or puts a foot down. Make sure subjects look at a non–moving target 4–12 feet ahead. Repeat other side.

*Patient:* Look straight ahead. Keep your hands on your hips. Bend one leg behind you. Do not touch your raised leg on your other leg. Stay standing on one leg as long as you can. Look straight ahead. Lift now.

4. **Compensatory stepping correction – forward**

*Examiner Instructions:* Stand in front to the side of patient with one hand on each shoulder and ask them to push forward. (Make sure there is room for them to step forward.) Require them to lean until their shoulders and hips are in front of their toes. The test must elicit a step. NOTE: Be prepared to catch patient.

*Patient:* Stand with your feet shoulder width apart, arms at your sides. Lean forward against my hands beyond your forward limits. When I let go, do whatever is necessary, including taking a step, to avoid a fall.

5. **Compensatory stepping correction – backward**

*Examiner Instructions:* Stand in back to the side of the patient with one hand on each scapula and ask them to lean backward. (Make sure there is room for them to step backward.) Require them to lean until their shoulders and hips are in back of their heels. After you feel their body weight in your hands, very suddenly release your support. Test must elicit a step. NOTE: Be prepared to catch patient.

*Patient:* Stand with your feet shoulder width apart, arms down at your sides. Lean backward against my hands beyond your backward limits. When I let go, do whatever is necessary, including taking a step, to avoid a fall.
6. Compensatory stepping correction – lateral
Examiner Instructions: Stand behind the patient, place one hand on either the right (or left) side of the pelvis, and ask them to lean their whole body into your hand. Require them to lean until the midline of pelvis is over the right (or left) foot and then suddenly release your hold. NOTE: Be prepared to catch patient.

Patient: Stand with your feet together, arms down at your sides the right (or left) side of the pelvis, and ask them to lean their whole body into your hand. Require them to lean until the midline of pelvis is over the right (or left) foot and then suddenly release your hold. NOTE: Lean into my hand beyond your sideways limit. When I let go, step if you need to, to avoid a fall.

7. Stance eyes open – firm surface
Examiner Instructions: Record the time the patient was able to stand with feet together up to a maximum of 30 seconds. Make sure subjects look at non-moving target 4–12 feet away.

Patient: Place your hands on your hips. Place your feet together until almost touching. Look straight ahead. Stay as stable as possible until I say stop.

8. Stance eyes closed – foam surface
Examiner Instructions: Use medium density Temper® foam, 4 inches thick. Assist subject in stepping onto foam. Tell patient to “Close Eyes”. Record the time the patient was able to stand in each condition to a maximum of 30 seconds. Have the subject step of the foam between trials.

Patient: Place your hands on your hips. Place your feet together until almost touching. Stay as stable as possible until I say stop. I will start timing when you close your eyes.

9. Incline – eyes closed
Examiner Instructions: Aid the patient onto the ramp. Once the patient closes their eyes, begin timing and record and average both times. Note if sway is greater than when standing on firm, level surface with eyes closed (Item 7) or if there is poor alignment to vertical.

Patient: Please stand on the incline ramp with your toes toward the top. Place your feet shoulder width apart and your arms on your hips. I will start timing when you close your eyes.

10. Change in speed
Examiner Instructions: Allow the patient to take 3–5 steps at their normal speed, and then say “fast”, after 3–5 fast steps once say “slow”. Allow 3–5 slow steps before they stop walking.

Patient: Begin walking at your normal speed, when I tell you “fast” walk as fast as you can. When I say “slow”, walk very slowly.

11. Walk with head turns – horizontal
Examiner Instructions: Allow the patient to reach their normal speed, and give the commands “right, left” every 3–5 steps. Score if you see a problem in either direction. If patient has severe cervical restrictions allow combined head and trunk movements.

Patient: Begin walking at your normal speed, when I say “right”, turn your head and look to the right. When I say “left” turn your head and look to the left. Try to keep yourself walking in a straight line.

12. Walk with pivot turns
Examiner Instructions: Demonstrate a pivot turn. Once the patient is walking at normal speed, say “turn and stop”. Count the steps from turn until the subject is stable. Imbalance may be indicated by wide stance width, extra stepping or trunk motion.

Patient: Begin walking at your normal speed. When I tell you to “turn and stop”, turn as quickly as you can to face the opposite direction and stop. After the turn, your feet should be close together.

13. Step over obstacles
Examiner Instructions: Place the box (9” / 22.9 cm height) 10 feet away from where the patient will begin walking. Use a stopwatch to time gait duration to calculate average velocity by dividing the number of seconds into 20 feet.

Patient: Begin walking at your normal speed. When you come to the shoe boxes (9” / 22.9 cm height), step over them, not around them and keep walking.

14. Timed get up & go (TUG) and cognitive get up & go with dual task
Examiner Instructions: Use the TUG score to determine the effects of dual tasking.

\textit{TUG}: Have the patient sit with their back against the chair. Time the patient from the time you say “Go” until they return to sitting in chair. Stop timing when the patient’s buttocks hit the chair bottom. The chair should be firm with arms to push from if necessary.

\textit{TUG with Dual Task}: While sitting, determine how fast and accurately the patient can count backwards by 3 seconds from a number between 90–100. Then, ask them to count from a different number and after a few numbers say “Go”. Time the patient from the time you say “Go” until they return to the sitting position. Score dual task as affecting walking if speed slows >10% from TUG &/or new signs of imbalance.

\textit{TUG}: Begin walking at your normal speed. When I say “Go”, stand up from chair, walk at your normal speed across the tape on the floor; turn around, and come back to sit in the chair. Continue counting backwards the entire time.

\textit{TUG with Dual Task}: Count backwards by 3 seconds starting at_. When I say “Go”, stand up from chair, walk at your normal speed across the tape on the floor, turn around, and come back to sit in the chair. Continue counting backwards the entire time.
